Aim of the lecture

- Our goal is to study (nonconstant) entire curves $f : \mathbb{C} \to X$ drawn in a projective variety/$\mathbb{C}$. The variety $X$ is said to be Brody ($\iff$ Kobayashi) hyperbolic if there are no such curves.

- More generally, if $\Delta = \sum \Delta_j$ is a reduced normal crossing divisor in $X$, we want to study entire curves $f : \mathbb{C} \to X \setminus \Delta$ drawn in the complement of $\Delta$.

If there are no such curves, we say that the log pair $(X, \Delta)$ is Brody hyperbolic.
Aim of the lecture (continued)

- Even more generally, if $\Delta = \sum (1 - \frac{1}{\rho_j}) \Delta_j \subset X$ is a normal crossing divisor, we want to study entire curves $f : \mathbb{C} \to X$ meeting each component $\Delta_j$ of $\Delta$ with multiplicity $\geq \rho_j$.

The pair $(X, \Delta)$ is called an orbifold (in the sense of Campana). Here $\rho_j \in ]1, \infty]$, where $\rho_j = \infty$ corresponds to the logarithmic case. Usually $\rho_j \in \{2, 3, ..., \infty\}$, but $\rho_j \in \mathbb{R}_{>1}$ will be allowed.

- The strategy is to show that under suitable conditions, orbifold entire curves must satisfy algebraic differential equations.

$k$-jets of curves and $k$-jet bundles

Let $X$ be a nonsingular $n$-dimensional projective variety over $\mathbb{C}$.

Definition of $k$-jets

For $k \in \mathbb{N}^*$, a $k$-jet of curve $f_{[k]} : (\mathbb{C}, 0)_k \to X$ is an equivalence class of germs of holomorphic curves $f : (\mathbb{C}, 0) \to X$, written $f = (f_1, \ldots, f_n)$ in local coordinates $(z_1, \ldots, z_n)$ on an open subset $U \subset X$, where two germs are declared to be equivalent if they have the same Taylor expansion of order $k$ at $0$:

$$f(t) = x + t \xi_1 + t^2 \xi_2 + \cdots + t^k \xi_k + O(t^{k+1}), \quad t \in D(0, \varepsilon) \subset \mathbb{C},$$

and $x = f(0) \in U$, $\xi_s \in \mathbb{C}^n$, $1 \leq s \leq k$.

Notation

Let $J^kX$ be the bundle of $k$-jets of curves, and $\pi_k : J^kX \to X$ the natural projection, where the fiber $(J^kX)_x = \pi_k^{-1}(x)$ consists of $k$-jets of curves $f_{[k]}$ such that $f(0) = x$. 
Algebraic differential operators

Let \( t \mapsto z = f(t) \) be a germ of curve, \( f_k = (f', f'', \ldots, f^{(k)}) \) its \( k \)-jet at any point \( t = 0 \). Look at the \( \mathbb{C}^* \)-action induced by dilations \( \lambda \cdot f(t) := f(\lambda t), \lambda \in \mathbb{C}^* \), for \( f_k \in J^k X \).

Taking a (local) connection \( \nabla \) on \( T_X \) and putting \( \xi_s = f(s)(0) = \nabla_s f(0) \), we get a trivialization \( J^k X \cong (T_X)^{\oplus k} \) and the \( \mathbb{C}^* \) action is given by

\[
(\ast) \quad \lambda \cdot (\xi_1, \xi_2, \ldots, \xi_k) = (\lambda \xi_1, \lambda^2 \xi_2, \ldots, \lambda^k \xi_k).
\]

We consider the Green-Griffiths sheaf \( E_{k,m}(X) \) of homogeneous polynomials of weighted degree \( m \) on \( J^k X \) defined by

\[
P(x; \xi_1, \ldots, \xi_k) = \sum a_{\alpha_1 \alpha_2 \ldots \alpha_k}(x) \xi_1^{\alpha_1} \cdots \xi_k^{\alpha_k}, \quad \sum_{s=1}^k s|\alpha_s| = m.
\]

Here, we assume the coefficients \( a_{\alpha_1 \alpha_2 \ldots \alpha_k}(x) \) to be holomorphic in \( x \), and view \( P \) as a differential operator \( P(f) = P(f; f', f'', \ldots, f^{(k)}) \),

\[
P(f)(t) = \sum a_{\alpha_1 \alpha_2 \ldots \alpha_k}(f(t)) f'(t)^{\alpha_1} f''(t)^{\alpha_2} \cdots f^{(k)}(t)^{\alpha_k}.
\]

Graded algebra of algebraic differential operators

In this way, we get a graded algebra \( \bigoplus_mE_{k,m}(X) \) of differential operators. As sheaf of rings, in each coordinate chart \( U \subset X \), it is a pure polynomial algebra isomorphic to

\[
\mathcal{O}_X[f_j^{(s)}]_{1 \leq j \leq n, 1 \leq s \leq k} \quad \text{where} \quad \deg f_j^{(s)} = s.
\]

If a change of coordinates \( z \mapsto w = \psi(z) \) is performed on \( U \), the curve \( t \mapsto f(t) \) becomes \( t \mapsto \psi \circ f(t) \) and we have inductively

\[
(\psi \circ f)^{(s)} = (\psi' \circ f) \cdot f^{(s)} + Q_{\psi,s}(f', \ldots, f^{(s-1)})
\]

where \( Q_{\psi,s} \) is a polynomial of weighted degree \( s \).

By filtering by the partial degree of \( P(x; \xi_1, \ldots, \xi_k) \) successively in \( \xi_k, \xi_{k-1}, \ldots, \xi_1 \), one gets a multi-filtration on \( E_{k,m}(X) \) such that the graded pieces are

\[
G^\bullet E_{k,m}(X) = \bigoplus_{\ell_1 + 2\ell_2 + \cdots + k\ell_k = m} S^{\ell_1} T_X^* \otimes \cdots \otimes S^{\ell_k} T_X^*.
\]
Logarithmic jet differentials

Take a logarithmic pair \((X, \Delta)\), \(\Delta = \sum \Delta_j\) normal crossing divisor.

Fix a point \(x \in X\) which belongs exactly to \(p\) components, say \(\Delta_1, \ldots, \Delta_p\), and take coordinates \((z_1, \ldots, z_n)\) so that \(\Delta_j = \{z_j = 0\}\).

\[\Rightarrow\] log differential operators: polynomials in the derivatives \((\log f_j(s))\), \(1 \leq j \leq p\) and \(f_j(s), \ p + 1 \leq j \leq n\).

Alternatively, one gets an algebra of logarithmic jet differentials, denoted \(\bigoplus_m E_{k,m}(X, \Delta)\), that can be expressed locally as \(O_X[(f_1)^{-1} f_1(s), \ldots, (f_p)^{-1} f_p(s), f_{p+1}(s), \ldots, f_n(s)]_{1 \leq s \leq k}\).

One gets a multi-filtration on \(E_{k,m}(X, \Delta)\) with graded pieces \(G^* E_{k,m}(X, \Delta) = \bigoplus_{\ell_1 + 2\ell_2 + \cdots + k\ell_k = m} S^{\ell_1} T_X^*(\Delta) \otimes \cdots \otimes S^{\ell_k} T_X^*(\Delta)\)

where \(T_X^*(\Delta)\) is the logarithmic tangent bundle, i.e., the locally free sheaf generated by \(\frac{dz_1}{z_1}, \ldots, \frac{dz_p}{z_p}, dz_{p+1}, \ldots, dz_n\).

Orbifold jet differentials

Consider an orbifold \((X, \Delta)\), \(\Delta = \sum (1 - \frac{1}{\rho_j})\Delta_j\) a SNC divisor.

Assuming \(\Delta_1 = \{z_1 = 0\}\) and \(f\) having multiplicity \(q \geq \rho_1 > 1\) along \(\Delta_1\), then \(f_1(s)\) still vanishes at order \(\geq (q - s)_+\), thus \((f_1)^{-\beta} f_1(s)\) is bounded as soon as \(\beta q \leq (q - s)_+\), i.e. \(\beta \leq (1 - \frac{s}{q})_+\). Thus, it is sufficient to ask that \(\beta \leq (1 - \frac{s}{q})_+\). At a point \(x \in |\Delta_1| \cap \cdots \cap |\Delta_p|\), the condition for a monomial of the form

\[(*) \quad f_1^{-\beta_1} \cdots f_p^{-\beta_p} \prod_{s=1}^k (f(s))^{\alpha_s}, \quad (f(s))^{\alpha_s} = (f_1(s))^{\alpha_{s,1}} \cdots (f_n(s))^{\alpha_{s,n}},\]

\(\alpha_s \in \mathbb{N}^n, \beta_1, \ldots, \beta_p \in \mathbb{N}\), to be bounded, is to require that

\[(**) \quad \beta_j \leq \sum_{s=1}^k \alpha_{s,j} \left(1 - \frac{s}{\rho_j}\right)_+, \quad 1 \leq j \leq p.\]

Definition

\(E_{k,m}(X, \Delta)\) is taken to be the algebra generated by monomials (*) of degree \(\sum s |\alpha_s| = m\), satisfying partial degree inequalities (**)
It is important to notice that if we consider the log pair \((X, [\Delta])\) with \([\Delta] = \sum \Delta_j\), then
\[
\bigoplus_m E_{k,m}(X, \Delta) \text{ is a graded subalgebra of } \bigoplus_m E_{k,m}(X, [\Delta]).
\]
The subalgebra \(E_{k,m}(X, \Delta)\) still has a multi-filtration induced by the one on \(E_{k,m}(X, [\Delta])\), and, at least for \(\rho_j \in \mathbb{Q}\), we formally have
\[
G^\bullet E_{k,m}(X, \Delta) \subset \bigoplus_{\ell_1+2\ell_2+\cdots+k\ell_k=m} S^{\ell_1} T^*_X(\Delta^{(1)}) \otimes \cdots \otimes S^{\ell_k} T^*_X(\Delta^{(k)}),
\]
where \(T^*_X(\Delta^{(s)})\) is the "\(s\)-th orbifold cotangent sheaf" generated by
\[
z_j^{-\left(1-s/\rho_j\right)+d^{(s)}z_j}, \quad 1 \leq j \leq p, \quad d^{(s)}z_j, \quad p+1 \leq j \leq n
\]
(which makes sense only after taking some Galois cover of \(X\) ramifying at sufficiently large order along \(\Delta_j\)).
Generalized Green-Griffiths-Lang conjecture

Generalized GGL conjecture (very optimistic ?)

If \((X, \Delta)\) is an orbifold of general type, in the sense that \(K_X + \Delta\) is a big \(\mathbb{R}\)-divisor, then there is a proper algebraic subvariety \(Y \subseteq X\) containing all orbifold entire curves \(f : \mathbb{C} \to (X, \Delta)\) (not contained in \(\Delta\) and having multiplicity \(\geq \rho_j\) along \(\Delta_j\)).

One possible strategy is to show that such orbifold entire curves \(f\) must satisfy a lot of algebraic differential equations of the form 
\[ P(f; f', ..., f^{(k)}) = 0 \] for \(k \gg 1\). This is based on:

Fundamental vanishing theorem

[Green-Griffiths 1979], [Demairy 1995], [Siu-Yeung 1996], ...

Let \(A\) be an ample divisor on \(X\). Then, for all global jet differential operators on \((X, \Delta)\) with coefficients vanishing on \(A\), i.e. 
\[ P \in H^0(X, E_{k,m}(X, \Delta) \otimes \mathcal{O}(-A)), \] and for all orbifold entire curves \(f : \mathbb{C} \to (X, \Delta)\), one has \(P(f[k]) \equiv 0\).

Proof of the fundamental vanishing theorem

Simple case. First consider the compact case \((\Delta = 0)\), and assume that \(f\) is a Brody curve, i.e. \(\|f'\|_\omega\) bounded for some hermitian metric \(\omega\) on \(X\). By raising \(P\) to a power, we can assume \(A\) very ample, and view \(P\) as a \(\mathbb{C}\) valued differential operator whose coefficients vanish on a very ample divisor \(A\).

The Cauchy inequalities imply that all derivatives \(f^{(s)}\) are bounded in any relatively compact coordinate chart. Hence \(u_A(t) = P(f[k])(t)\) is bounded, and must thus be constant by Liouville’s theorem.

Since \(A\) is very ample, we can move \(A \in |A|\) such that \(A\) hits \(f(\mathbb{C}) \subset X\). But then \(u_A\) vanishes somewhere, and so \(u_A \equiv 0\).

Logarithmic and orbifold cases. In the orbifold case, one must use instead an “orbifold metric” \(\omega\). Removing the hypothesis \(f'\) bounded is more tricky. One possible way is to use the Ahlfors lemma and some representation theory.
Holomorphic Morse inequalities

**Theorem (D, 1985, L. Bonavero 1996)**

Let $L \to X$ be a holomorphic line bundle on a compact complex manifold. Assume $L$ equipped with a singular hermitian metric $h = e^{-\varphi}$ with analytic singularities in $\Sigma \subset X$, and $\theta = \frac{i}{2\pi} \Theta_L, h$. Let

$$X(\theta, q) := \{ x \in X \setminus \Sigma; \theta(x) \text{ has signature } (n - q, q) \}$$

be the $q$-index set of the $(1,1)$-form $\theta$, and

$$X(\theta, \leq q) = \bigcup_{j \leq q} X(\theta, j).$$

Then

$$\sum_{j=0}^{q} (-1)^{q-j} h_j(X, L^{\otimes m} \otimes I(m\varphi)) \leq \frac{m^n}{n!} \int_{X(\theta, \leq q)} (-1)^q \theta^n + o(m^n),$$

where $I(m\varphi) \subset \mathcal{O}_X$ denotes the multiplier ideal sheaf

$$I(m\varphi)_x = \{ f \in \mathcal{O}_{X,x}; \exists U \ni x \text{ s.t. } \int_U |f|^2 e^{-m\varphi} dV < +\infty \}.$$

Holomorphic Morse inequalities [continued]

**Consequence of the holomorphic Morse inequalities**

For $q = 1$, with the same notation as above, we get a lower bound

$$h^0(X, L^{\otimes m}) \geq h^0(x, L^{\otimes m} \otimes I(m\varphi)) \geq h^0(x, L^{\otimes m} \otimes I(m\varphi)) - h^1(x, L^{\otimes m} \otimes I(m\varphi)) \geq \frac{m^n}{n!} \int_{X(\theta, \leq 1)} \theta^n - o(m^n).$$

here $\theta$ is a real $(1,1)$ form of arbitrary signature on $x$.

when $\theta = \alpha - \beta$ for some explicit $(1,1)$-forms $\alpha, \beta \geq 0$ (not necessarily closed), an easy lemma yields

$$1_{X(\alpha - \beta, \leq 1)} (\alpha - \beta)^n \geq \alpha^n - n\alpha^{n-1} \wedge \beta$$

hence

$$h^0(X, L^{\otimes m}) \geq \frac{m^n}{n!} \int_X (\alpha^n - n\alpha^{n-1} \wedge \beta) - o(m^n).$$
Finsler metric on the $k$-jet bundles

Assume that $T_X$ is equipped with a $C^\infty$ connection $\nabla$ and a hermitian metric $h$. One then defines a "weighted Finsler metric" on $J^k X$ by taking $b = \text{lcm}(1, 2, \ldots, k)$ and, at each point $x = f(0)$,

$$\Psi_{h_k}(f[k]) := \left( \sum_{1 \leq s \leq k} \varepsilon_s \|\nabla^s f(0)\|_h^{2b/s} \right)^{1/b}, \quad 1 = \varepsilon_1 >> \varepsilon_2 >> \cdots >> \varepsilon_k.$$  

Letting $\xi_s = \nabla^s f(0)$, this can be viewed as a metric $h_k$ on $L_k := O_{X_k}(1)$, and the curvature form of $L_k$ is obtained by computing

$$i \frac{2\pi}{\partial \bar{\partial}} \log \Psi_{h_k}(f[k])$$

as a function of $(x, \xi_1, \ldots, \xi_k)$. Modulo negligible error terms of the form $O(\varepsilon_s^{s+1}/\varepsilon_s)$, this gives

$$\Theta_{L_k, h_k} = \omega_{FS, k}(\xi) + i \frac{2\pi}{\partial \bar{\partial}} \log \Psi_{h_k}(f[k]) \quad \text{where} \quad \omega_{FS, k}(\xi) = \omega_{FS, k}(\xi) + \frac{1}{2} \sum_{1 \leq s \leq k} \frac{1}{s} \sum_{t \leq s} \frac{|\xi_t|^{2b/s}}{|\xi_s|^{2b/t}} \sum_{i,j,\alpha,\beta} c_{ij,\alpha,\beta}(z) u_s u_{s\bar{s}} \bar{u}_s \bar{u}_{s\bar{s}} \ dz_i \wedge d\bar{z}_j$$

where $(c_{ij,\alpha,\beta})$ are the coefficients of the curvature tensor $\Theta_{T^*_X, h^*}$ and $\omega_{FS, k}$ is the weighted Fubini-Study metric on the fibers of $X_k \to X$.

Evaluation of Morse integrals

The above expression is simplified by using polar coordinates

$$x_s = |\xi_s|_h^{2b/s}, \quad u_s = \frac{\xi_s}{|\xi_s|_h} = \frac{\nabla^s f(0)}{|\nabla^s f(0)|}.$$  

In such polar coordinates, one gets the formula

$$\Theta_{L_k, h_k} = \omega_{FS, k}(\xi) + i \frac{2\pi}{\partial \bar{\partial}} \sum_{1 \leq s \leq k} \frac{1}{s} x_s \sum_{i,j,\alpha,\beta} c_{ij,\alpha,\beta}(z) u_s u_{s\bar{s}} \bar{u}_s \bar{u}_{s\bar{s}} \ dz_i \wedge d\bar{z}_j$$

where $\omega_{FS, k}(\xi)$ is positive definite in $\xi$.

By holomorphic Morse inequalities, we need to evaluate an integral

$$\int_{X_k(\Theta_{L_k, h_k}, \leq 1)} \Theta^{N_k}_{L_k, h_k}, \quad N_k = \dim X_k = n + (kn - 1),$$

and we have to integrate over the parameters $z \in X$, $x_s \in \mathbb{R}_+$ and $u_s$ in the unit sphere bundle $\mathbb{S}(T_X, 1) \subset T_X$.

Since the weighted projective space can be viewed as a circle quotient of the pseudosphere $\sum |\xi_s|^{2b/s} = 1$, we can take here $\sum x_s = 1$, i.e. $(x_s)$ in the $(k - 1)$-dimensional simplex $\Delta^{k-1}$.
Probabilistic interpretation of the curvature

Now, the signature of \( \Theta_{L_k,h_k} \) depends only on the vertical terms, i.e.

\[
\sum_{1 \leq s \leq k} \frac{1}{s} x_s q(u_s), \quad q(u_s) := \frac{i}{2\pi} \sum_{i,j,\alpha,\beta} c_{ij\alpha\beta}(z) u_{s\alpha} \overline{u}_{s\beta} \, dz \wedge d\overline{z}.
\]

After averaging over \((x_s) \in \Delta^{k-1}\) and computing the rational number

\[
\int \omega_{FS,k}(\xi)^{nk-1} = \frac{1}{(k!)^n},
\]

what is left is to evaluate Morse integrals with respect to \((u_s)\) of “horizontal” \((1,1)\)-forms given by sums \(\sum \frac{1}{s} q(u_s)\), where \(u_s\) are “random points” on the unit sphere.

As \(k \to +\infty\), this sum yields asymptotically a “Monte-Carlo” integral

\[
\left(1 + \frac{1}{2} + \cdots + \frac{1}{k}\right) \int_{u \in \mathbb{S}(T_X,1)} q(u) \, du.
\]

Since \(q\) is quadratic in \(u\), we have

\[
\int_{u \in \mathbb{S}(T_X,1)} q(u) \, du = \frac{1}{n} \text{Tr}(q)
\]

and

\[
\text{Tr}(q) = \text{Tr}(\Theta_{T^*_X,h^*}) = \Theta_{\text{det} T^*_X,\text{det} h^*} = \Theta_{K_X,\text{det} h^*}.
\]

Probabilistic cohomology estimate

**Theorem 1 (D-, Pure and Applied Math. Quarterly 2011)**

Fix \(A\) ample line bundle on \(X\), \((T_X, h), (A, h_A)\) hermitian structures on \(T_X, A\), and \(\omega_A = \Theta_{A,h_A} > 0\). Let \(\eta_\varepsilon = \Theta_{K_X,\text{det} h^*} - \varepsilon \omega_A\) and

\[
L_k = \mathcal{O}_X(1) \otimes \pi_k^* \mathcal{O}_X \left( - \frac{1}{kn} \left(1 + \frac{1}{2} + \cdots + \frac{1}{k}\right) \varepsilon A \right), \quad \varepsilon \in \mathbb{Q}_+.
\]

Then for \(m\) sufficiently divisible, we have a lower bound

\[
h^0(X_k, L_k \otimes^m) = h^0\left(X, E_{k,m}(X) \otimes \mathcal{O}_X \left( - \frac{m\varepsilon}{kn} \left(1 + \frac{1}{2} + \cdots + \frac{1}{k}\right) A \right) \right)
\geq \frac{m^{n+kn-1}}{(n + kr - 1)! \, n! \, (k!)^n} \left( \int_X (\eta_\varepsilon - \frac{C}{\log k}) \right).
\]

**Corollary**

If \(K_X\) is big and \(\varepsilon > 0\) is small, then \(\eta_\varepsilon\) can be taken > 0, so

\[
h^0(X_k, L_k \otimes^m) \geq C_{n,k,\eta,\varepsilon} \, m^{n+kn-1}
\]

with \(C_{n,k,\eta,\varepsilon} > 0\), for \(m \gg k \gg 1\).

There are in fact similar upper/lower bounds for all \(h^q(X_k, L_k \otimes^m)\).
Non probabilistic cohomology estimate

The Monte-Carlo estimate can be replaced by a non probabilistic one, if one assumes an explicit lower bound for the curvature tensor

$$\Theta_{T^*_X, h^*} \geq -\gamma \otimes \text{Id},$$

where $\gamma \geq 0$ is a smooth $(1, 1)$-form on $X$.

In case $X \subset \mathbb{P}^N$ and $A = O(1)$, one can always take $\gamma = 2\omega_A$ where $\omega_A = \Theta_{A, h_A} > 0$.

By Morse inequalities for differences $1_X(\alpha - \beta, \leq 1)(\alpha - \beta)^n$, one gets

Assume $k \geq n$ and $m \gg 1$. With the same notation as in Theorem 1, the dimensions $h^0(X_k, L^\otimes m_k)$ are bounded below by

$$\frac{m^{n+kn-1}}{n!k!(n+kn-1)!} \int_X (\Theta_{K_X + n\gamma})^n - c_{n,k}(\Theta_{K_X + n\gamma})^{n-1} \wedge (\varepsilon \omega_A + n\gamma),$$

with $c_{n,k} \in \mathbb{Q}_{>0}$ explicit, $c_{n,k} \leq 4^{n-1}n!(1 + \frac{1}{2} + \cdots + \frac{1}{k})^n$.

Logarithmic situation

In the case of a log pair $(X, \Delta)$, one reproduce essentially the same calculations, by replacing the cotangent bundle $T^*_X$ with the logarithmic cotangent bundle $T^*_X(\Delta)$. This gives

**Theorem 3 (probabilistic estimate)**

Put $\eta_\varepsilon = \Theta_{K_X + \Delta, \det h^*} - \varepsilon \omega_A$. For $m \gg k \gg 1$, the dimensions

$h^0(X, E_k, m(X, \Delta) \otimes O_X(-\frac{m}{kn}(1 + \frac{1}{2} + \cdots + \frac{1}{k})A))$

are bounded below by

$$\frac{m^{n+kn-1}}{(n+kr-1)! \cdot n!(k)!^n} \left( \int_{X(\eta, \leq 1)} \eta_\varepsilon^n - \frac{C}{\log k} \right), \quad C > 0.$$

**Theorem 4 (non probabilistic estimate)**

Assume $\Theta_{T^*_X(\Delta)} \geq -\gamma \otimes \text{Id}$. For $k \geq n, m \gg 1$, there are bounds

$$\frac{m^{n+kn-1}}{n!k!(n+kn-1)!} \int_X (\Theta_{K_X + \Delta + n\gamma})^n - c_{n,k}(\Theta_{K_X + \Delta + n\gamma})^{n-1} \wedge (\varepsilon \omega_A + n\gamma).$$
Orbifold situation

Consider now the orbifold case \((X, \Delta)\), \(\Delta = \sum (1 - \frac{1}{\rho_j}) \Delta_j\).

In this case, the solution is to work on the logarithmic projectivized jet bundle \(X_k \langle \lceil \Delta \rceil \rangle\), with Finsler metrics \(\Psi_{h_k}(f_k)\) of the form

\[
\left( \sum_{1 \leq s \leq k} \varepsilon_s \left( \sum_{j=1}^{p} |f_j|^{-2(1-s/p_j)} + |f_j^{(s)}(0)|^2 + \sum_{j=p+1}^{n} |f_j^{(s)}(0)|^2 \right)^{b/s} h_s(f(0)) \right)^{1/b},
\]

where \(h_s\) is a hermitian metric on the \(s\)-th orbifold bundle \(T^{*}_X \langle \Delta^{(s)} \rangle\).

**Theorem 5** (non probabilistic estimate [probabilistic doesn’t work])

Assume \(\Theta_{T^*_X \langle \Delta^{(s)} \rangle} \geq -\gamma_s \omega \otimes \text{Id}\) in the sense of Griffiths, with \(\omega = \Theta_A\) \((A \text{ ample})\), \(\gamma_s \geq 0\), and let \(\Theta_s = \Theta_{K_X + \Delta^{(s)}}\) for \(s = 1, \ldots, k\). Then, for \(k \geq n\) and \(m \gg 1\),

\[
h_0(X, E_{k,m}(X, \Delta) \otimes O_X(-m \varepsilon A)) \geq \frac{m^{n+kn-1}}{n!(k!)^n(n+kn-1)!} \left[ \int_X \bigwedge_{s=1}^{n} (\Theta_s + n\gamma_s \omega) - \frac{(2n-1)!}{(n-1)!^2} \times \left( \sum_{s=1}^{k} \frac{\gamma_s}{s} \right) \left( \sum_{s=1}^{k} \frac{1}{s} (\Theta_s + n\gamma_s \omega) \right)^{n-1} \wedge \omega - O(\varepsilon) \right].
\]

**Application to projective space**

Consider \(\mathbb{P}^n\) equipped with an orbifold divisor \(\Delta = \sum_{j=1}^{N} (1 - \frac{1}{\rho_j}) \Delta_j\).

**Lemma: lower bound on the curvature of the cotangent bundle**

Put \(A = O_{\mathbb{P}^n}(1)\), \(d_j = \deg \Delta_j\) and \(\gamma_0 = \max \left( \frac{d_j}{\rho_j}, 2 \right)\). Then \(\forall \gamma > \gamma_0\), there exists a suitable hermitian metric on \(T^*_{\mathbb{P}^n} \langle \Delta \rangle\) such that

\[
\Theta_{T^*_X \langle \Delta \rangle} + \gamma \omega_A \otimes \text{Id} > 0 \quad \text{(in the sense of Griffiths)}.
\]

**Corollary: sufficient condition of existence of orbifold differentials**

A sufficient condition for the existence of negatively twisted orbifold order \(k = n\) jet differentials on \(\mathbb{P}^n \langle \Delta \rangle\) is

\[
\rho_j \geq \rho > n, \quad \sum_{j=1}^{N} d_j \geq c_n \max \left( \frac{d_j}{\rho_j}, 2 \right) \prod_{s=1}^{n} \left( 1 - \frac{s}{\rho} \right)^{-1}.
\]

with \(c_n = O((2n \log n)^n)\) an explicit constant.

Example: \(N = 1, \rho_1 \geq 2c_n, d_1 \geq 4c_n\).
Generalization: case of orbifold directed varieties

One can also consider a smooth directed variety \((X, V)\) with a subbundle or subsheaf \(V \subset T_X\) (e.g. a foliation), equipped with an orbifold divisor \(\Delta\) transverse to \(V\).

One then looks at entire curves \(f : \mathbb{C} \to X\) that are tangent to \(V\) and satisfy the ramification conditions specified by \(\Delta\).

It is possible to define orbifold directed structures \(V\langle\Delta^{(s)}\rangle \subset T_X\langle\Delta^{(s)}\rangle\) and corresponding jet differential bundles \(E_{k,m}(X, V, \Delta)\).

**Theorem 6**

An existence criterion for sections of \(E_{k,m}(X, V, \Delta)\) holds as well.

Thank you for your attention!
